# 1 GENERAL

## 1.1 Description of SIN Beam

The SIN beam is a corrugated web welded I-shaped steel beam with a corrugated steel web welded to flat steel flanges.

SIN Beams may be used as flexural members such as roof or floor beams, as components subjected to axial loads such as columns, or as combined bending and axial members such as in moment frames or wind columns. The optimal application for the SIN beam is as an alternative to a rolled or welded wide flange shape or a joist or joist girder section with a depth between 12 in. and 70 in. (300 mm and 1800 mm).

Traditionally the shear strength of a thin web steel beam has been governed by web buckling. Web stiffeners can be used to avoid web buckling but are costly to install. The sinusoidal shape of the SIN beam web prevents such buckling, eliminating the need for web stiffeners, and allowing the web steel material to reach its shear yield strength.

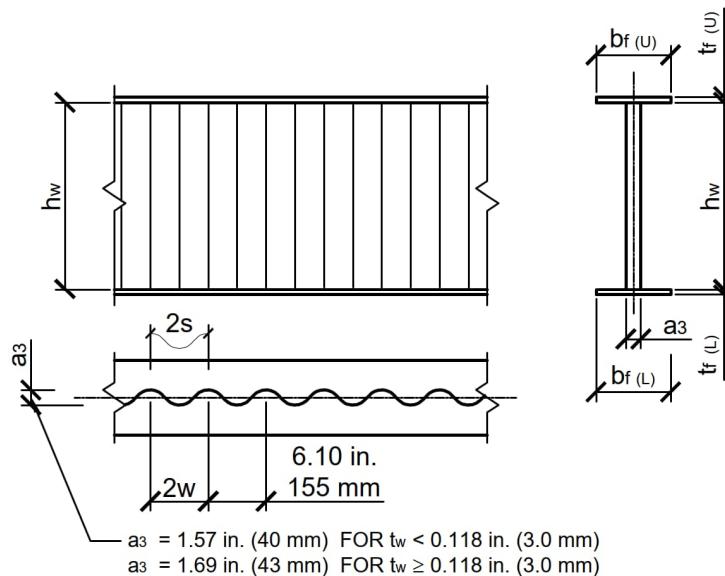

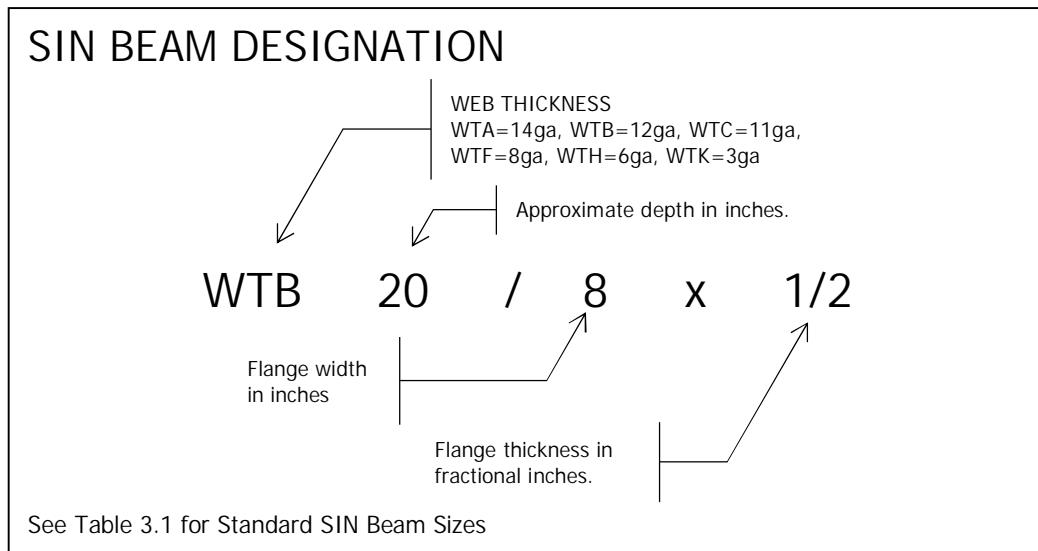

Figure 1: Corrugated Web Steel Beam

### 1.1.1 Designation:

The standard designation for a parallel flange SIN beam is:

WT [web\_thickness] [web\_height] / [flange\_width] x [flange\_thickness]

Example: WTB 20 / 8 x 1/2

## 1.2 Basis for Calculations

The strength of the SIN beam in bending, axial and shear forces is described in detail in Section 2 of this guide. The bending and axial strength of the SIN beam is based on the design requirements provided in ANSI/AISC 360-16 (A360) "Specification for Structural Steel Buildings" [1]. The web of the SIN beam is made of cold-formed steel and therefore the shear strength is established based on ANSI/AISI S100-16 (S100) "North American Specification for the Design of Cold-Formed Steel Structural Members" [2].

Due to the sinusoidal shape, the web has a negligible contribution to the axial strength of the SIN beam flanges. The axial forces in the beam (due to axial load or a bending moment couple) are carried solely by the SIN beam flanges. The corrugated web resists the beam shear forces and stabilizes the flanges. As such the SIN beam behaves similar to a truss or joist, where the axial and bending forces are carried by the chords (flanges) and the shear forces are carried by the web diagonals (corrugated web).

The SIN beam strength has been confirmed by a number of experimental results and expert opinions, some of which are included in Section 5 of this guide.

## 1.3 Product Range

Standard SIN beam members are composed of a uniform height, corrugated steel web and two flat steel flanges of equal size. Other configurations, including different top and bottom flanges or tapered webs, are also available. SIN beam sections can be manufactured in lengths between 13 ft (3.96 m) and 50 ft (15.2 m). The standard configurations and designations are described in this section and listed in table 3.1.

### 1.3.1 Beam Components

#### 1.3.1.1 Web

The SIN beam web is manufactured from steel coil material which is cold-formed into the corrugated shape. The standard coil widths used to manufacture SIN beam webs are between 13 in. (333 mm) and 60 in. (1500 mm). These coils are available in thicknesses ranging from 0.0748 in. (1.90 mm) to 0.239 in. (6.07 mm).

Standard coils can be used to create the following standard web heights:

- 13 = 13.1 in. (333 mm)
- 20 = 19.7 in. (500 mm)
- 24 = 24.0 in. (610 mm)
- 30 = 29.5 in. (750 mm)
- 36 = 35.4 in. (900 mm)
- 40 = 39.4 in. (1000 mm)
- 48 = 48.0 in. (1219 mm)
- 60 = 59.1 in. (1500 mm)

The web thicknesses and associated designations are as follows:

- A : 0.0748 in. [14 ga] (1.90 mm)
- B : 0.105 in. [12 ga] (2.66 mm)
- C : 0.120 in. [11 ga] (3.04 mm)
- F : 0.164 in. [8 ga] (4.17 mm)
- H : 0.194 in. [6 ga] (4.93 mm)
- K : 0.239 in. [3 ga] (6.07 mm)

The corrugated web follows a sinusoidal shape with a wave length of 6.10 in. (155 mm) and an amplitude of 1.57 in. (40 mm) for web thicknesses less than 0.118 in. (3 mm) or 1.69 in. (43 mm) for web thicknesses greater than 0.118 in. (3 mm), see Figure 1. The web is continuously fillet welded to both beam flanges by robotic welding equipment, on one side of the web.

#### 1.3.1.2 Flange

The flanges are fabricated of flat stock material or de-stressed coil material with thickness ranging from  $\frac{1}{4}$  in. (6.35 mm) to  $1\frac{1}{2}$  in. (38.1 mm) and in widths between 5 in. (127 mm) and 17.7 in. (450 mm).

For all standard size SIN beams the ratio of the flange width to thickness is such that the beam is

considered compact (C) or non-compact (NC) as per A360, Table 3.3a and 3.3b indicate the section classification. A list of standard sizes is included in Table 3.1 of this guide.

Due to the availability of materials flanges  $\frac{3}{4}$  in. (19.1 mm) and thicker and longer than 40 ft (12.2 m) will be spliced with full penetration welds.

## 1.4 Material

The standard material for both flange and web steel is ASTM A572 Gr 50. Other steel grades can also be used but would be considered a special order and would require longer procurement times, minimum order quantities and premium pricing. SIN beam members are fabricated to the tolerances given in ASTM A6 for rolled or welded wide flange steel shapes.

## 1.5 Welding

All welding is AWS D.1 & D1.3 compliant and done by procedures approved by the American Welding Society (AWS). Welding procedures are included in part 5 of this guide. The corrugated web is welded to the flanges using a continuous fillet weld on one side of the web.

## 1.6 Corrosion Protection / Painting

SIN beam members are available in any of the following conditions:

- Raw Steel – if special coatings including fireproofing are to be applied.
- Shop Primer
- Hot-Dip Galvanized

## 1.7 List of Symbols / Abbreviations

$a_3$	amplitude of the SIN beam web corrugation (see 1.1)
$A_g$	gross area of beam flanges
$A_v$	shear area
$A_{v, eff}$	effective shear area, adjusted to account for the corrugated profile of the web, is used for shear deflection calculations
A360	ANSI/AISC 360-16 Specification for Structural Steel Buildings
$b_f$ (U) or (L)	width of the SIN beam flange (Upper or Lower)
$C_w$	warping torsional constant
d	overall depth of a SIN beam member
E	Young's Modulus (For A360 E = 29,000 ksi; for S100 E = 29,500 ksi)
ENC	EN 1993-1-5:2006 European code for plated steel elements
$F_y$	specified minimum steel yield stress
G	shear Modulus (For A360 G = 11,200 ksi; for S100 G = 11,300 ksi)

$h_w$	height of the SIN beam web (i.e. between the flanges)
$I_x, I_y$	moment of inertial about the strong axis / weak axis
$J$	St. Venant torsional constant
$L_p$	longest unbraced length where the beam will reach its full moment strength
M/D	mass over heated perimeter (kg / m / m) per UL
$M_n$	nominal flexural strength
$P_n$	nominal axial strength
$r_x, r_y$	radius of gyration with respect to the strong / weak axis
$s$	unfolded length of half of a single wave of the SIN beam corrugation
S100	ANSI S100-16 North American specification for the design of cold-formed steel structural members
$S_x, S_y$	elastic section modulus about the strong axis / weak axis
$t_f$ (U) or (L)	thickness of the SIN beam flange (upper or lower)
$t_w$	SIN beam web thickness
$t_{w, eff}$	SIN beam effective web thickness, adjusted to account for the corrugated profile of the web, is used for weight and shear deflection calculations
UL	Underwriters Laboratory
$V_n$	nominal shear strength
$w$	length of half of a single wave of the SIN beam corrugation
w/d	weight over heated perimeter (lb / ft / in.) per UL
WTA, WTB, WTC, WTF, WTH, WTK	– SIN Beam web thickness designation (see 1.3.1.1)
$\Omega_b$	ASD safety factor for flexure = 1.67
$\Omega_c$	ASD safety factor for compression = 1.67
$\Omega_v$	ASD safety factor for shear = 2.0
$\phi_b$	LRFD resistance factor for flexure = 0.9
$\phi_c$	LRFD resistance factor for compression = 0.9
$\phi_v$	LRFD resistance factor for shear = 0.8
$\nu$	Poisson's ratio = 0.3
$\chi_{c,l}, \chi_{c,g}$	reduction factor for local and global buckling

## 2 TECHNICAL SECTION

### 2.1 Flexural Strength

The SIN beam flexural strength can be calculated based on the formula given in Section F5 of A360. Due to the nature of the corrugated beam web, the web material has an insignificant contribution to the flexural strength of the member and is ignored.

The limiting width to thickness ratio for the SIN beam compression flange is determined based on Table B4.1b Case 11 of A360. Based on this the thin web,  $k_c$  value is taken as 0.35 for all SIN beam members. The width  $b$  is taken as  $b = \frac{1}{2}b_f$ .

Standard SIN beam section properties and flexural strength are given Section 3 of this guide.

#### 2.1.1 Deflection Calculations

Because of the thin and deep web of the SIN beam member, shear deformations will be larger than for conventional rolled wide flange shapes and should be considered for accurate deflection calculations. The beam shear area for each web height and thickness is included in Section 3, and can be used to calculate the shear deformation of the SIN beam.

For common beam sizes (i.e. less than 36.0 in. (914 mm) in depth) and typical beam spans, the shear deflection typically increase the deflection by 5 to 15%. Shear deformation increases linearly with beam length while flexural deformation increases rapidly as a third power to beam length. Therefore, shear deformations are most significant for beams with low span to depth ratios.

In section 2.6 of Blodgett [4] there is an expression for the calculation of shear deformation of steel beams. Shear deflection is related to the beam loading, span, shear area and modulus of elasticity. Equations are presented for shear deformation due to uniform or point loads on simply supported and cantilever sections. The shear deformation can be added to the beam flexural deformation to determine the total beam deflection. A shear deflection calculation based on Blodgett's formula has been included in the example problem in Section 1 of this guide.

### 2.2 Shear Strength

Since the SIN beam web material is made of cold-formed steel, the shear design of the beam is based on S100. The governing shear design criteria in Section G of S100 is based on the web material being uniform thickness and not of a corrugated geometric shape. Therefore, in the case of the SIN Beam, a

direct shear strength calculation cannot be made based on Section G2.1 of S100. However, Section A1.2(c) does permit the use of a *"Rational Engineering Analysis"* based on appropriate theory and engineering judgment.

### 2.2.1 Shear Strength – Rational Engineering Analysis

A shear strength design method for corrugated beam webs has been developed in Europe in the 1990s based on theory/research and extensive testing. This design expression has been adopted by the European Code ENC [3] and is contained in Annex D, a copy of which is included in section 5 of this guide. Given the well-established history in Europe, the method was adopted as the Rational Engineering Analysis as per Section A1.2(c) of S100 for the SIN beam. In addition, confirmatory tests were carried out to verify the accuracy of the method. As well, for LRFD the resistance factor is 0.80 and the safety factor for ASD is 2.00.

### 2.2.2 Annex D of ENC [3]

Annex D provides expressions for the shear design of corrugated web beams which accounts for yielding, local buckling, or global buckling of a corrugated web. The basic nominal shear expression of Annex D is:

$$V_n = \chi_c \frac{f_y}{\gamma_{M1}\sqrt{3}} h_w t_w$$

$\chi_c$  is the lesser of the local or global buckling coefficient  $\chi_{c,l}$  or  $\chi_{c,g}$

$\gamma_{M1}$  is the partial factor equal to 1.0 (the appropriate LRFD or ASD factor will be applied per S100)

$\frac{f_y}{\sqrt{3}} = 0.577 f_y$  as per von Mises yield theory which is similar to the  $0.6 F_y$  used in A360 and S100

$h_w t_w = A_w$  is the area of the web

In the European code material resistance factors are left up to each country and not included in the code formula.

Local Buckling

$$\chi_{c,l} = \frac{1.15}{0.9 + \bar{\lambda}_{c,l}} \leq 1.0$$

$$\bar{\lambda}_{c,l} = \sqrt{\frac{F_y}{\tau_{cr,l} \cdot \sqrt{3}}}$$

$$\tau_{cr,l} = \left( 5.34 + \frac{a_3 S}{h_w t_w} \right) \frac{\pi^2 E}{12(1-\nu^2)} \left( \frac{t_w}{s} \right)^2$$

$a_3$  - Web amplitude

$S$  - unfolded length of one half wave

$E$  – Young's modulus

$\nu$  – Poisson's Ratio

Global Buckling

$$\chi_{c,g} = \frac{1.5}{0.5 + \bar{\lambda}_{c,g}^2} \leq 1.0$$

$$\bar{\lambda}_{c,g} = \sqrt{\frac{F_y}{\tau_{cr,g} \cdot \sqrt{3}}}$$

$$\tau_{cr,g} = \frac{32.4}{t_w h_w^2} \sqrt[4]{D_x D_z^3}$$

$$D_x = \frac{E t^3}{12(1-\nu^2)} \frac{w}{s}$$

$$D_z = \frac{E I_z}{w}$$

w - length of one half wave

$I_z$  - second moment of area of one corrugation of length w

### 2.2.3 Shear Strength – Load Testing

Steelcon has conducted shear load testing, in accordance with Section K of S100 for a selection of SIN beam members to ensure the accuracy of the design method in ENC [3] Annex D. A report by Dr. R.M. Schuster of the shear load testing is included in Section 5 of this guide. The SIN Beam shear load testing has shown that the shear expression is conservative, as can be observed from the conclusion of the test report.

## 2.3 Axial Strength

The axial strength of a SIN beam section can be determined by formula in A360 sections E3, E4, & E7. Similar to the flexural resistance the axial resistance is provided solely by the steel area of the flanges (neglecting any contribution of the web).

The limiting width to thickness ratio for the SIN beam flanges is determined based on Table B4.1a Case 2 of A360 since the thin web  $k_c$  value is taken as 0.35 for all SIN beam members. The width b is taken as  $b = \frac{1}{2} b_f$ . Some SIN beam flanges are considered slender per Table B4.1a, for these members the axial strength is calculated per Section E7, the table for axial strength in Section 3 of this guide indicates if the member is slender (S) or non-slender (NS).

## 2.4 Detailed Calculation

Below is a detailed member strength calculation for flexure, shear and axial strength of a SIN beam member. Equation and Section references from A360 or S100 are in (italics).

### 2.4.1 Input

$$\begin{array}{llll} F_y = 50 \text{ ksi} & \mu = 0.3 & \phi_b = 0.9 & \phi_c = 0.9 \\ E = 29,000 \text{ ksi} & G = 11,170 \text{ ksi} & \Omega_b = 1.67 & \Omega_c = 1.67 \\ \text{SIN Beam Size } & \boxed{\text{WTC 20 / 8 x } \frac{1}{2}} & & \Omega_v = 2.00 \end{array}$$

Web Properties       $h_w = 19.68 \text{ in.}$      $t_w = 0.1196 \text{ in.}$      $a_3 = 1.69 \text{ in.}$      $w = 3.05 \text{ in.}$

Flange Properties       $b_f = 8 \text{ in.}$        $t_f = \frac{1}{2} \text{ in.}$

Unbraced Length

$L_b = 10 \text{ ft}$       Bending Lateral-Torsional Buckling

$L_c = 20 \text{ ft}$       Compression Flexural Buckling

$L_{cz} = 20 \text{ ft}$       Compression Torsional Buckling

### 2.4.2 A360 Flexural Strength (Section F5)

#### 2.4.2.1 Compression Flange Yielding

$R_{pg} = 1.0$  – The web has no contribution to the flexural strength  $a_w = 0$

$$I_x = 2 \left( \frac{1}{12} b_f t_f^3 + b_f t_f \left( \frac{1}{2} h_w + \frac{1}{2} t_f \right)^2 \right) = 2 \left( \frac{1}{12} 8 \times 0.5^3 + 8 \times 0.5 \left( \frac{1}{2} 19.68 + \frac{1}{2} 0.5 \right)^2 \right) = 815 \text{ in}^4$$

$$S_{xc} = \frac{I_x}{\frac{1}{2}(t_f + h_w + t_f)} = \frac{815}{\frac{1}{2}(0.5 + 19.68 + 0.5)} = 78.8 \text{ in}^3 \quad I_x \text{ and } S_x \text{ are based on the flanges only}$$

$$M_n = R_{pg} F_y S_{xc} = 1.0 \times 50 \times 78.8 = 328 \text{ kip-ft} \quad - (F5-1)$$

#### 2.4.2.2 Lateral-Torsional Buckling

$$r_t = \frac{b_f}{\sqrt{12 \left( 1 + \frac{1}{6} \times a_w \right)}} = \frac{8}{\sqrt{12}} = 2.31 \text{ in.} \quad - (F4-11) \quad a_w = 0$$

$$L_p = 1.1 \times r_t \sqrt{\frac{E}{F_y}} = 1.1 \times 2.31 \sqrt{\frac{29,000}{50}} = 61.2 \text{ in.} \quad - (F4-7)$$

$$L_r = \pi \times r_t \sqrt{\frac{E}{0.7 \times F_y}} = 3.14 \times 2.31 \sqrt{\frac{29,000}{0.7 \times 50}} = 209 \text{ in.} \quad - (F5-5)$$

$$C_b = 1.0$$

$L_b = 10 \text{ ft} = 120 \text{ in.}$      $L_p < L_b < L_r$  therefore  $F_{cr}$  is based on (F5-3)

$$F_{cr} = C_b \left( F_y - 0.3 \times F_y \frac{L_b - L_p}{L_r - L_p} \right) = 1.0 \left( 50 - 0.3 \times 50 \frac{120 - 61.2}{209 - 61.2} \right) = 44.0 \text{ ksi} < 50 \text{ ksi} \quad - (F5-3)$$

$$M_n = R_{pg} F_{cr} S_{xc} = 1.0(44.0)(78.8) = 289 \text{ kip-ft} \quad - (F5-2)$$

### 2.4.2.3 Compression Flange Local Buckling

$$\lambda_p = 0.38 \sqrt{\frac{E}{F_y}} = 0.38 \sqrt{\frac{29,000}{50}} = 9.15 \quad - (\text{Table B4.1b - Case 11})$$

$$k_c = 0.35$$

$$F_L = 0.7F_y = 0.7(50) = 35 \text{ ksi} \quad - \text{Since } S_{xt} = S_{xc}$$

$$\lambda_r = 0.95 \sqrt{\frac{k_c E}{F_L}} = 0.95 \sqrt{\frac{0.35 \times 29,000}{35}} = 16.2 \quad - (\text{Table B4.1b - Case 11})$$

$$\lambda = \frac{b_f}{2 t_f} = \frac{8}{2 \times 0.5} = 8 \quad \lambda < \lambda_p \text{ Therefore } F_{cr} = F_y$$

$$M_n = R_{pg} F_{cr} S_{xc} = 1.0(50)(78.8) = 328 \text{ kip-ft} \quad - (F5-7)$$

### 2.4.2.4 Tension Flange Yielding

Does not apply as  $S_{xt} = S_{xc}$

### 2.4.2.5 Flexural Strength

Nominal Flexural Strength is the minimum of the values for Compression Flange Yielding (*F5-1*), Lateral-Torsional Buckling (*F5-2*) and Compression Flange Buckling (*F5-7*)

$$M_n = 289 \text{ kip-ft}$$

#### Design Flexural Strength (LRFD)

$$\phi_b M_n = 0.9(289) = 260 \text{ kip-ft} \quad (\text{see Table 3.3b})$$

#### Allowable Flexural Strength (ASD)

$$\frac{M_n}{\Omega_b} = \frac{289}{1.67} = 173 \text{ kip-ft} \quad (\text{see Table 3.3a})$$

### 2.4.3 S100 Shear Strength

Based on Rational Engineering Analysis, S100 Section A1.2(c), and ENC [4] (Annex D)

$$V_n = \chi_c \frac{F_y}{\sqrt{3}} h_w t_w$$

$$S = \frac{1}{2} \int_0^{2w} \sqrt{1 + \left( \frac{a_3 \pi}{2w} \times \sin\left(\frac{2\pi x}{2w}\right) \right)^2} dx = \frac{1}{2} \int_0^{2 \times 3.05} \sqrt{1 + \left( \frac{1.69 \pi}{2 \times 3.05} \times \sin\left(\frac{2\pi x}{2 \times 3.05}\right) \right)^2} dx = 3.57 \text{ in.}$$

### 2.4.3.1 Local Buckling Coefficients

$$\tau_{cr,I} = \left( 5.34 + \frac{a_3 s}{h_w t_w} \right) \frac{\pi^2 E}{12(1-\mu^2)} \left( \frac{t_w}{s} \right)^2 = \left( 5.34 + \frac{1.69 \times 3.57}{19.7 \times 0.120} \right) \frac{\pi^2 29,500}{12(1-0.3^2)} \left( \frac{0.120}{3.57} \right)^2 = 237 \text{ ksi}$$

$$\lambda_{c,I} = \sqrt{\frac{F_y}{\tau_{cr,I} \sqrt{3}}} = \sqrt{\frac{50}{237\sqrt{3}}} = 0.349$$

$$\chi_{c,l} = \frac{1.15}{0.9 + \lambda_{c,l}} = \frac{1.15}{0.9 + 0.349} = 0.921$$

#### 2.4.3.2 Global Buckling Coefficients

$$I_z = \frac{1}{2} \int_0^{2w} \left( \frac{1}{12} t_w^3 + t_w \left( \frac{a_3}{2} \sin \left( \frac{2\pi x}{2w} \right) \right)^2 \right) dx$$

$$= \frac{1}{2} \int_0^{2 \times 3.05} \left( \frac{1}{12} 0.1196^3 + 0.1196 \left( \frac{1.69}{2} \sin \left( \frac{2\pi x}{2 \times 3.05} \right) \right)^2 \right) dx = 0.131 \text{ in}^4$$

$$D_z = \frac{EI_z}{w} = \frac{29,500 \times 0.131}{3.05} = 1270 \text{ kip-in.}$$

$$D_x = \frac{E t_w^3 w}{12(1-\mu^2) s} = \frac{29,500 \times 0.1196^3}{12(1-0.3^2)} \times \frac{3.05}{3.57} = 3.95 \text{ kip-in}$$

$$\tau_{cr,g} = \frac{32.4}{t_w \times h_w} \times \sqrt[4]{D_x \times D_z^3} = \frac{32.4}{0.1196 \times 19.68^2} \times \sqrt[4]{3.95 \times 1270^3} = 209 \text{ ksi}$$

$$\lambda_{c,g} = \sqrt{\frac{F_y}{\tau_{cr,g}\sqrt{3}}} = \sqrt{\frac{50}{209\sqrt{3}}} = 0.371$$

$$\chi_{c,g} = \frac{1.5}{0.5 + \lambda_{c,g}^2} = \frac{1.5}{0.5 + 0.371^2} = 2.35 \text{ but } \chi_{c,g} \leq 1.0 \therefore \chi_{c,g} = 1.0$$

$\chi_c$  is the minimum of  $\chi_{c,l}$  for Local Buckling and  $\chi_{c,g}$  for Global Buckling  $\therefore \chi_c = 0.921$

#### 2.4.3.3 Shear Strength

$$V_n = \chi_c \frac{F_y}{\sqrt{3}} h_w t_w = 0.921 \frac{50}{\sqrt{3}} 19.68 \times 0.1196 = 62.6 \text{ kip}$$

##### Design Shear Strength (LRFD)

$$\phi V_n = 0.8(62.6) = 50.1 \text{ kip} \quad (\text{see Table 3.4b})$$

##### Allowable Shear Strength (ASD)

$$\frac{V_n}{\Omega_v} = \frac{62.6}{2.0} = 31.3 \text{ kip} \quad (\text{see Table 3.4a})$$

#### 2.4.4 A360 Axial Strength (*Section E3, E4, E7*)

$$k_c = 0.35$$

$$\lambda_r = 0.64 \sqrt{\frac{k_c E}{F_y}} = 0.64 \sqrt{\frac{0.35 \times 29,000}{50}} = 9.12 \quad - (\text{Table B4.1a - Case 2})$$

$$\lambda = \frac{0.5 b_f}{t_f} = \frac{0.5 \times 8}{0.5} = 8 \quad - \text{As } \lambda < \lambda_r \text{ this section is non-slender and section E3 and E4 apply}$$

$$d = h_w + 2 \times t_f = 19.7 + 2 \times 0.5 = 20.7 \text{ in.}$$

$$A = 2 \times b_f \times t_f = 2 \times 8 \times 0.5 = 8 \text{ in}^2$$

$$I_x = 2 \left( \frac{1}{12} b_f t_f^3 + b_f t_f \left( \frac{1}{2} h_w + \frac{1}{2} t_f \right)^2 \right) = 2 \left( \frac{1}{12} 8 \times 0.5^3 + 8 \times 0.5 \left( \frac{1}{2} 19.68 + \frac{1}{2} 0.5 \right)^2 \right) = 815 \text{ in}^4$$

$$I_y = \frac{1}{12} b_f^3 d - \frac{1}{12} b_f^3 h_w = \frac{1}{12} 8^3 \times 20.7 - \frac{1}{12} 8^3 \times 19.7 = 42.7 \text{ in}^4$$

$$r_x = \sqrt{\frac{I_x}{A}} = \sqrt{\frac{815}{8}} = 10.1 \text{ in.} \quad r_y = \sqrt{\frac{I_y}{A}} = \sqrt{\frac{42.7}{8}} = 2.31 \text{ in.} \quad r_x/r_y = 10.1/2.31 = 4.37$$

$$J = \frac{2 \times b_f \times t_f^3}{3} = \frac{2 \times 8 \times 0.5^3}{3} = 0.667 \text{ in}^4$$

$$C_w = \frac{(d-t_f)^2 \times b_f^3 \times t_f}{24} = \frac{(20.7-0.5)^2 \times 8^3 \times 0.5}{24} = 4350 \text{ in}^6$$

#### 2.4.4.1 Flexural Buckling – Section E3

$$F_e = \frac{\pi^2 E}{\left(\frac{L_c}{r_y}\right)^2} = \frac{\pi^2 29,000}{\left(\frac{240}{2.31}\right)^2} = 26.5 \text{ ksi} \quad \frac{F_y}{F_e} = \frac{50}{26.5} = 1.89 \leq 2.25$$

$$F_{cr} = \left( 0.658 \frac{F_y}{F_e} \right) F_y = \left( 0.658 \frac{50}{26.5} \right) 50 = 22.7 \text{ ksi} \quad (E3-2)$$

$$P_n = F_{cr} \times A_g = 22.7 \times 8 = 182 \text{ kip}$$

#### 2.4.4.2 Torsional Buckling – Section E4

$$F_e = \left( \frac{\pi^2 E \times C_w}{L_{cz}^2} + G \times J \right) \frac{1}{I_x + I_y} = \left( \frac{\pi^2 29,000 \times 4350}{240^2} + 11,200 \times 0.667 \right) \frac{1}{815 + 42.7} = 33.9 \text{ ksi} \quad (E4-2)$$

$$\frac{F_y}{F_e} = \frac{50}{33.9} = 1.47 \leq 2.25$$

$$F_{cr} = \left( 0.658 \frac{F_y}{F_e} \right) F_y = \left( 0.658 \frac{50}{33.9} \right) 50 = 27.0 \text{ ksi} \quad (E3-2)$$

$$P_n = F_{cr}(A_g) = 27.0(8) = 216 \text{ kip}$$

#### 2.4.4.3 Axial Strength

Nominal Axial Strength is the minimum value of Flexural Buckling (E3) and Torsional Buckling (E4)

$$P_n = 182 \text{ kip}$$

#### Design Axial Strength

$$\phi_c P_n = 0.9(182) = 163 \text{ kip} \quad (\text{see Table 3.5b})$$

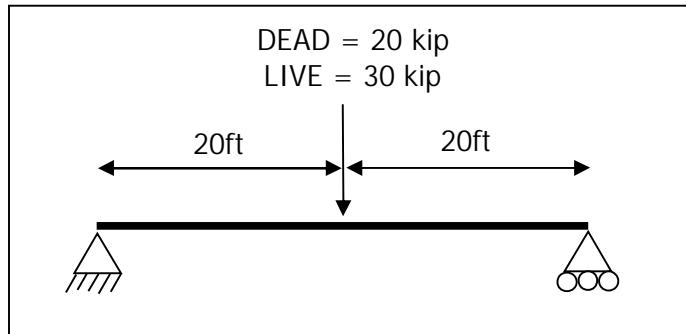

#### Allowable Axial Strength

$$\frac{P_n}{\Omega_c} = \frac{182}{1.67} = 109 \text{ kip} \quad (\text{see Table 3.5a})$$

## 2.5 Sample Problem

This sample problem is intended as a quick introduction to using the design tables contained in this guide. This beam will be designed using the LRFD strength design approach. For a typical SIN beam design there are 3 independent parameters to determine, web height, web thickness and flange size. Flexural strength and flexural deflection are related to the web height and flange size, and shear strength and shear deflection are related to the web height and web thickness.

### 2.5.1 Input Parameters

A 40 ft long simply supported beam is loaded at mid span with a 20 kip dead and 30 kip live load. The beam is laterally restrained at the supports and at mid span. Design the beam that is less than 36 in. in depth to resist the applied loads and to have a live load deflection of less than L/360.

### 2.5.2 Strength Check

#### LRFD Factored Load Effects

$$\text{Factored point load } P_f = 1.2 \text{ DL} + 1.6 \text{ LL} = 1.2(20) + 1.6 (30) = \underline{72 \text{ kip}}$$

$$\text{Factored mid-span moment } M_f = \frac{1}{4} P_f L = \frac{1}{4} 72 \times 40 = \underline{720 \text{ kip-ft}}$$

$$\text{Factored shear load } V_f = \frac{1}{2} P_f = \frac{1}{2} 72 = \underline{36 \text{ kip}}$$

To have the final beam size be less than 36 in. in depth we will use a WT\_30 SIN beam which has a 29.5 in. tall web. The flange size and web thickness can be selected such that the design flexural strength and design shear strength exceed the factored load effects.

The flange size can be selected based on Table 3.3b. The LRFD design flexural strength of a **WT\_30 / 10 x 1** is 814 kip-ft for an unbraced length of 20 ft.

The web thickness can be selected based on Table 3.4b. The LRFD design shear strength of a **WTB 30** is 62.3 kip

Therefore a **WTB 30 / 10 x 1** is structurally sufficient to resist the design loads

### 2.5.3 Deflection Check

The Live Load deflection limit is  $L/360 = 40(12)/360 = \underline{1.33 \text{ in.}}$

#### 2.5.3.1 Flexural Deflection

From Table 3.2a the strong axis moment of inertia for a **WT\_ 30 / 10 x 1** is  $I_x = 4660 \text{ in}^4$

$$\Delta_f = \frac{P L^3}{48 E I_x} = \frac{30 \times 480^3}{48 \times 29,000 \times 4660} = \underline{0.511 \text{ in.}}$$

#### 2.5.3.2 Shear Deflection

From "Design of Welded Structures" by O.W. Blodgett [4] the shear deflection is calculated as

$$\Delta_v = \frac{P L \alpha}{4 A v E_s}, \text{ in Blodgett's nomenclature } E_s \text{ is the Shear modulus G}$$

$\alpha$  is a form factor for an I or box beam  $\alpha = \frac{A}{8 I_x t_w} (b_f d^2 - b_f h_w^2 + t_w h_w^2)$  most of these physical properties for a **WTB 30 / 10 x 1** can be found in Table 3.2, the web effective shear area  $A_v$  can be found in Table 3.4c

$$\alpha = \frac{3.62}{8 \times 4660 \times 0.105} (10 \times 31.5^2 - 10 \times 29.5^2 + 0.105 \times 29.5^2) = \underline{1.21}$$

$$\Delta_v = \frac{30 \times 480 \times 1.21}{4 \times 3.62 \times 11300} = \underline{0.106 \text{ in.}}$$

#### 2.5.3.3 Total Deflection

The total beam deflection is the summation of the flexural plus the shear deflection of the beam.

$$\Delta = \Delta_f + \Delta_v = 0.511 + 0.106 = 0.617 \text{ in.} < L/360 = \underline{1.33 \text{ in.}}$$

### 2.5.4 Results Summary

The SIN beam that satisfies the design criteria is therefore a **WTB 30 / 10 x 1**

Per Table 3.2a the overall depth is 31.5 in.

Per Table 3.3b the design flexural strength is 814 kip-ft

Per Table 3.4b the design shear strength is 62.3 kip

The resulting total deflection is 0.617 in.

#### Table Notes

Table 3.3 • NC, C indicates if the section is Non-Compact or Compact in Flexure per A360 Table B4.1b Case 11

Table 3.5 • NS, S indicates if the section is Non-Slender or Slender in Axial Compression per A360 Table B4.1a Case 2

Table 3.6 • Per current UL / ULC listings all SIN beam webs must have a minimum thickness of 0.120 in. (3.04 mm) which is a WTC or heavier, thinner webs are shown in grey italics

• Per the BXUV Guide the minimum w/d ratio is 0.37, smaller values are shown in red

• Per the BXUVC Guide the minimum M/D ratio is 23, smaller values are shown in red

• These values are for UL / ULC Beam design formula and exclude the top of the top flange in the perimeter calculation

• There are currently no UL / ULC designs for SIN members used as column sections

## Common SIN Beam Sizes

**Notes:**

Per current UL / ULC listings all SIN beam webs must have a minimum thickness of 0.120 in. (3.04 mm)  
 which is a WTC or heavier, thinner webs are shown in grey italics

Per the BXUV Guide the minimum w/d ratio is 0.37, smaller values are shown in red

Per the BXUVC Guide the minimum M/D ratio is 23, smaller values are shown in red

## Annex D [informative] – Plate girders with corrugated webs

### D.1 General

- (1) Annex D covers design rules for I-girders with trapezoidally or sinusoidally corrugated webs, see Figure D.1.

**Figure D.1: Geometric notations**

### D.2 Ultimate limit state

#### D.2.1 Moment of resistance

- (1) The moment of resistance  $M_{Rd}$  due to bending should be taken as the minimum of the following:

$$M_{Rd} = \min \left\{ \underbrace{\frac{b_2 t_2 f_{yw,r}}{\gamma_{M0}} \left( h_w + \frac{t_1 + t_2}{2} \right)}_{\text{tension flange}}, \underbrace{\frac{b_1 t_1 f_{yw,r}}{\gamma_{M0}} \left( h_w + \frac{t_1 + t_2}{2} \right)}_{\text{compression flange}}, \underbrace{\frac{b_1 t_1 \chi f_{yw}}{\gamma_{M1}} \left( h_w + \frac{t_1 + t_2}{2} \right)}_{\text{compression flange}} \right\} \quad (\text{D.1})$$

where  $f_{yw,r}$  is the value of yield stress reduced due to transverse moments in the flanges

$$f_{yw,r} = f_{yw} f_T$$

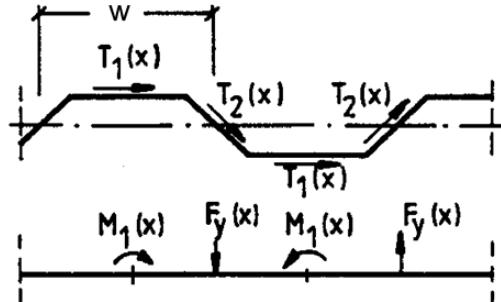

$$f_T = 1 - 0,4 \sqrt{\frac{\sigma_x(M_z)}{\frac{f_{yf}}{\gamma_{M0}}}}$$

$\sigma_x(M_z)$  is the stress due to the transverse moment in the flange

$\chi$  is the reduction factor for out of plane buckling according to 6.3 of EN 1993-1-1

**NOTE 1** The transverse moment  $M_z$  results from the shear flow in flanges as indicated in Figure D.2.

**NOTE 2** For sinusoidally corrugated webs  $f_T$  is 1,0.

**Figure D.2: Transverse moments  $M_z$  due to shear flow introduction into the flange**

(2) The effective area of the compression flange should be determined from 4.4(1) and (2) using the larger value of the slenderness parameter  $\bar{\lambda}_p$  defined in 4.4(2) and the buckling factor  $k_\sigma$  taken as:

$$a) \quad k_\sigma = 0,43 + \left( \frac{b}{a} \right)^2 \quad (D.2)$$

where  $b$  is the maximum width of the outstand from the toe of the weld to the free edge

$$a = a_1 + 2a_4$$

$$b) \quad k_\sigma = 0,60 \quad (D.3)$$

$$\text{where } b = \frac{b_1}{2}$$

### D.2.2 Shear resistance

(1) The shear resistance  $V_{Rd}$  should be taken as:

$$V_{Rd} = \chi_c \frac{f_{yw}}{\gamma_{M1} \sqrt{3}} h_w t_w \quad (D.4)$$

where  $\chi_c$  is the lesser of the values of reduction factors for local buckling  $\chi_{c,\ell}$  and global buckling  $\chi_{c,g}$  obtained from (2) and (3)

(2) The reduction factor  $\chi_{c,\ell}$  for local buckling should be calculated from:

$$\chi_{c,\ell} = \frac{1,15}{0,9 + \bar{\lambda}_{c,\ell}} \leq 1,0 \quad (D.5)$$

$$\text{where } \bar{\lambda}_{c,\ell} = \sqrt{\frac{f_y}{\tau_{cr,\ell} \sqrt{3}}} \quad (D.6)$$

$$\tau_{cr,\ell} = 4,83 E \left[ \frac{t_w}{a_{max}} \right]^2 \quad (D.7)$$

$a_{max}$  should be taken as the greater of  $a_1$  and  $a_2$ .

**prEN 1993-1-5 : 2005 (E)**

For sinusoidally corrugated webs  $\tau_{cr,\ell}$  may be obtained from

$$\tau_{cr,l} = \left( 5,34 + \frac{a_3 s}{h_w t_w} \right) \frac{\pi^2 E}{12(1-v^2)} \left( \frac{t_w}{s} \right)^2 \quad (D.8)$$

where  $w$  length of one half wave, see Figure D.1,

$s$  unfolded length of one half wave, see Figure D.1.

(3) The reduction factor  $\chi_{c,g}$  for global buckling should be taken as

$$\chi_{c,g} = \frac{1,5}{0,5 + \bar{\lambda}_{c,g}} \leq 1,0 \quad (D.9)$$

$$\text{where } \bar{\lambda}_{c,g} = \sqrt{\frac{f_y}{\tau_{cr,g} \sqrt{3}}} \quad (D.10)$$

$$\tau_{cr,g} = \frac{32,4}{t_w h_w^2} \sqrt[4]{D_x D_z^3} \quad (D.11)$$

$$D_x = \frac{E t^3}{12(1-v^2)} \frac{w}{s}$$

$$D_z = \frac{E I_z}{w}$$

$I_z$  second moment of area of one corrugation of length  $w$ , see Figure D.1

**NOTE 1**  $s$  and  $I_z$  are related to the actual shape of the corrugation.

**NOTE 2** Equation (D.11) is valid for plates that are assumed to be hinged at the edges.

### D.2.3 Requirements for end stiffeners

(1) Bearing stiffeners should be designed according to section 9.

## 13 Annex D to EN 1993-1-5 – Plate girders with corrugated webs

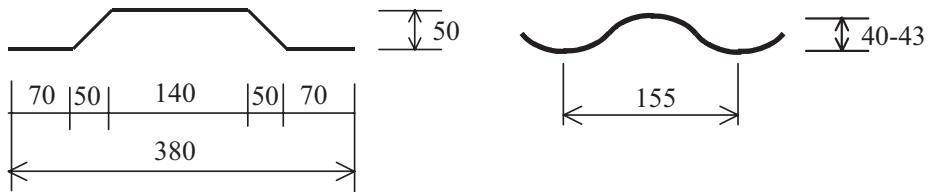

*Bernt Johansson, Division of Steel Structures, Luleå University of Technology*

### 13.1 Background

This section will give background and justification of the design rules for girders with corrugated webs. The rules have been developed during the drafting of EN 1993-1-5 and the background has not been published. For this reason this section will be quite detailed giving the reasoning behind the choice of design rules for shear resistance.

Girders with corrugated webs are marketed as a product from specialised fabricators or as one-off structures. One example of the former is Ranabalken, which has been on the Swedish market for about 40 years [1]. Its main use is as roof girder. It has a web geometry that is fixed because of the production restraints. A vertical section through the web is shown in Figure 13.1. The thickness of the web is minimum 2 mm, which is governed by the welding procedure. The welding is single sided, which is important for the competitiveness. The maximum depth is 3 m.

In Austria the company Zeman & Co is producing similar beams named Sin-beam but with sinusoidally corrugated webs with the web geometry also shown in Figure 13.1. The web depth is limited to 1500 mm and the web thickness is from 2 to 3 mm. The web has single sided welds.

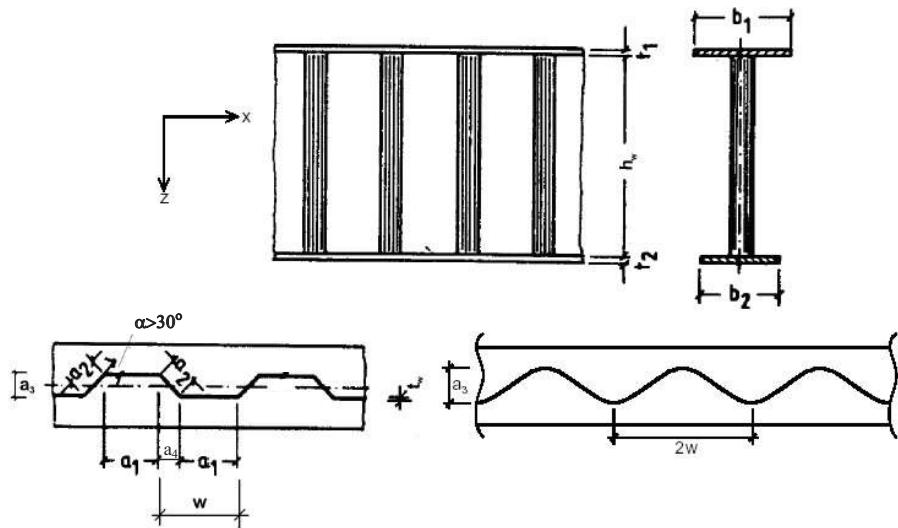

**Figure 13.1: Geometry of web plate of Ranabalken, Sweden and Sin-beam, Austria**

Corrugated webs have been used for bridges in several countries, including France, Germany and Japan. In France at least three composite bridges have been built of which one was doubly composite with box section. The corrugated steel web was provided with very small flanges, just enough for fixing the shear connectors. The concrete slabs were post-tensioned and when it is important that the steel flanges do not offer too much resistance to the imposed strains. A similar but larger bridge has been built at Altwipfergrund in Germany. It is a three span bridge built by cantilevering with a central span of 115 m and the depth varies from 2,8 m in the span to 6 m at the intermediate supports. The use of single sided welds is not recommended for bridges as it would cause problems with the corrosion protection and the fatigue resistance is not documented.

### 13.2 Bending moment resistance

As the web is corrugated it has no ability to sustain longitudinal stresses. The conventional assumption is to ignore its contribution to the bending moment resistance. This is the basis for the rules in D.2.1. For a simply supported girder supporting a uniformly distributed load the bending resistance is simply the smallest axial resistances of the flanges times the distance between the centroids of the flanges. This axial resistance may be influenced by lateral torsional buckling if the compression flange is not braced closely enough. Reference is given to the rules in 6.3 of EN 1993-1-1. There may be a positive influence of the corrugated web on the lateral bucking resistance compared to a flat web as the corrugation gives the web a substantial transverse bending stiffness. This should reduce the influence of cross sectional distortion but this influence has not been studied in detail and there is no basis for giving rules. There is also an increase in warping stiffness that may be utilized.

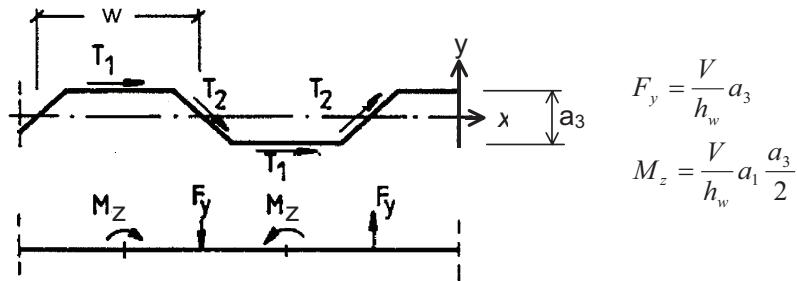

**Figure 13.2: Geometry and notations for girders with corrugated webs**

If there is a substantial shear force in the cross section of maximum bending moment there may be an influence of the flange axial resistance from lateral bending. Rules for this have been included in the German design rules [2]. A model for calculating these secondary bending moments is shown in Figure 13.3. The shear flow in the web will be constant  $V/h_w$  and its effect can be modelled as shown in the lower part of Figure 13.3. The maximum transverse bending moment  $M_{z,\max}$  occurs where the inclined part of the web intersects the centreline of the flange. It becomes:

$$M_{z,\max} = \frac{Va_3}{4h_w}(2a_1 + a_4) \quad (13.1)$$

where  $V$  is the coexisting shear force and other notations are according to Figure 13.2.

EN 1993-1-5,  
D.2.1

**Figure 13.3: Action model for calculating secondary lateral bending moments in a flange caused by a corrugated web**

In [2] the reduction of the bending resistance is expressed by the factor:

$$f_T = 1 - 0,4 \sqrt{\frac{6M_{z,\max}\gamma_{M0}}{f_{yf}b_f^2 t_f}} \quad (13.2)$$

This reduction is not large and actually it has not been considered in the Austrian and Swedish design rules. From a theoretical point of view these bending moments are required for reasons of equilibrium. However, it is questionable how important they actually are in real life. They have been included just as a precaution but for sinusoidally corrugated webs the factor is put to 1,0.

In case yielding of the flange governs the bending resistance becomes:

$$M_{Rd} = \frac{f_{yf} f_T b_f t_f}{\gamma_{M0}} \left( h_w + \frac{t_1 + t_2}{2} \right) \quad (13.3)$$

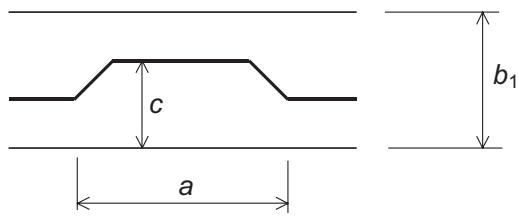

where  $b_f t_f$  should be taken as the smaller of  $b_1 t_1$  and  $b_2 t_2$ .

Local flange buckling is of importance for the bending resistance. It will obviously be influenced by the geometry of the web. The question is to define the flange outstand  $c$  to be used for calculating the slenderness. There is little information on this question in the literature. One of few published studies is by Johnson & Cafolla [3] who suggested that the average outstand could be used if:

$$\frac{(a_1 + a_4)a_3}{(a_1 + 2a_4)b_1} < 0,14 \quad (13.4)$$

where  $b_1$  is the width of the compression flange and other notations are according to Figure 13.2. It is not stated what to do if this criterion is not fulfilled but presumably the idea is to use the larger outstand. The average outstand was defined as the average of the smaller and the larger outstand each calculated from free edge to the toe of the weld.

EN 1993-1-5,  
D.2.1(2)

**Figure 13.4: Notations for flange geometry**

The design rules for Ranabalken states that the outstand should be taken as half the flange width minus 30 mm. This is actually smaller than the smallest outstand, which seems quite optimistic. The corresponding rule for the Sin-beam is half the flange width minus 11 mm.

The flange buckling may in general take place in two different modes. One possibility is a plate type buckling of the larger outstand and another is a torsional buckling where the flange rotates around the centreline of the web. General rules without restrictions on the geometry have to consider both possibilities. The first mode may be relevant for a long corrugation in combination with a narrow flange for which the larger outstand will govern the buckling. However, the flange will be supported by the inclined parts of the web. Assuming an equivalent rectangular plate supported along three edges a safe approximation of the relevant length should be  $a = a_1 + 2a_4$ , see Figure 13.2 and Figure 13.4. The buckling coefficient of such a plate assuming conservatively a hinged support along the web is approximately [4]:

$$k_\sigma = 0,43 + (c/a)^2 \quad (13.5)$$

with:

$c$  = largest outstand from weld to free edge

$$a = a_1 + 2a_4$$

For a geometry with small corrugations compared to the flange width the flange will buckle in a mode of rotation around the centreline of the web. Then  $c$  is taken to  $0,5b$ . A corrugated web will however give a stronger restraint than a flat web. The buckling coefficient ranges from 0,43 for simple support to 1,3 for fixed. A solution for elastic rotational restraint is given in [4] but it is not easy to use. A simplification in form of a reasonably conservative value is instead suggested, which is also used in [2]:

$$k_\sigma = 0,60 \quad (13.6)$$

The rules for flange buckling in 4.4 (1) and (2) of EN 1993-1-5 are used with the buckling coefficients given above together with the relevant outstand  $c$ . In general, both (13.5) and (13.6) have to be checked and the most unfavourable case governs.

### 13.3 Shear resistance

#### 13.3.1 Introduction

The shear resistance of corrugated webs has attracted interest from many researcher. Accordingly, there are several proposals for the shear resistance e. g. Leiva [5], Lindner [6], Höglund [7] and Johnson & Cafolla [8]. These will be compared with 70 test results presented in Table 13.1. The formulae for the shear resistance actually used in EN 1993-1-5 were developed during the evaluation. This work was done in close co-operation with Professor Torsten Höglund of the Royal Institute of Technology, Stockholm. He was in charge of the corresponding rules in EN 1999-1-1, which are now harmonized with EN 1993-1-5.

Notations for the corrugated web are shown in Figure 13.2. For the sinusoidally corrugated web the measures  $a_3$  and  $2w$  are relevant and the developed length of one full wave is denoted  $2s$ . For the trapezoidal web the following relations and definitions apply.

$$a_2 = a_3 / \sin \alpha$$

$$a_4 = a_3 \cot \alpha$$

$$w = a_1 + a_4$$

$$s = a_1 + a_2$$

$t_w$  = thickness of web

$h_w$  = depth of web

$$a_{\max} = \max(a_1, a_2)$$

There are two shear buckling modes; one local governed by the largest flat panel and one global involving one or more corrugations. The critical stress for local buckling is taken as that for a long plate, which can be written as:

$$\tau_{cr,\ell} = 4,83 E \left[ \frac{t_w}{a_{\max}} \right]^2 \quad (13.7)$$

For a sinusoidally corrugated web the local buckling is less likely to occur. A formula for critical shear stress for local buckling of webs with dimension as given in Figure 13.1 can be found in [19] and reads:

$$\tau_{cr,l} = \left( 5,34 + \frac{a_3 s}{h_w t_w} \right) \frac{\pi^2 E}{12(1-\nu^2)} \left( \frac{t_w}{s} \right)^2 \quad (13.8)$$

This formula was developed for the type of corrugation used in an Austrian girder but it has turned out that the formula is not general enough and the formula may give large errors if the dimensions are different to those given in Figure 13.1. For this reason sinusoidially corrugated webs have to be designed by testing with regard to local shear buckling where dimensions other than those given in Figure 13.1 are used. There is also a possibility to calculate the critical shear stresses for local buckling with FEM and to use it in the design rules given here.

The critical stress for global buckling is given by [9]:

$$\tau_{cr,g} = \frac{32,4}{t_w h_w^2} \sqrt[4]{D_x D_z^3} \quad (13.9)$$

EN 1993-1-5,  
D.2.2

where:

$$D_x = \frac{Et_w^3}{12(1-\nu^2)} \frac{w}{s} = \frac{Et_w^3}{12(1-\nu^2)} \frac{a_1 + a_4}{a_1 + a_2} \quad (13.10)$$

$$D_z = \frac{EI_z}{w} = \frac{Et_w a_3^2}{12} \frac{3a_1 + a_2}{a_1 + a_4} \quad (13.11)$$

The first versions of the formulae (13.10) and (13.11) are relevant for sinusoidally corrugated webs where  $I_z$  is the second moment of area of one half wave. The second versions are relevant for trapezoidally corrugated webs.

Both critical stresses are valid for simply supported long plates. The global buckling stress is derived from orthotropic plate theory, see e. g. [9]. Some authors have defined  $D_x$  without the factor  $(1-\nu^2)$  in the denominator. It is theoretically more correct to include it as in (13.10). In [9] there is also a solution for restrained rotation along the edge. For fully clamped edges the coefficient 32,4 in (13.9) increases to 60,4. This has been used for evaluating tests e. g. in [5] but it is hard to believe that this corresponds to the actual conditions at tests. The flanges are not likely to be rigid enough to provide a rotational restraint for such a stiff plate as a corrugated web. In this evaluation (13.9) will be used throughout.

Slenderness parameters are defined by:

$$\lambda_i = \sqrt{\frac{f_{yw}}{\tau_{cri} \sqrt{3}}} \quad (13.12)$$

for  $i = 1,2,3$  there 1 and 2 refers to equations (13.8) and (13.9) and 3 to equation (13.14) below.

Values for the slenderness parameters  $\lambda_1$  and  $\lambda_2$  for the test girders are given in Table 13.1. The characteristic shear resistance is represented by:

$$V_R = \chi \frac{f_{yw}}{\sqrt{3}} h_w t_w \quad (13.13)$$

where  $\chi$  is the minimum of the reduction values  $\chi_i$  determined for  $\lambda_1$  and  $\lambda_2$ .

The ultimate shear resistance  $V_u$  in the tests can be transformed to the non-dimensional parameter  $\chi_u$  by equation (13.13) and it is also given in Table 13.1.

The parameters defined above are general and will be used throughout the analysis. The features of the different models will now be described briefly and evaluated.

### 13.3.2 Model according to Leiva [5]

Leiva does not fully develop a design model but his main concern is the interaction between local and global buckling, which is based on observations from tests. His idea is to consider this interaction by defining a combined critical stress  $\tau_{cr3}$  as:

$$\frac{1}{\tau_{cr3}^n} = \frac{1}{\tau_{cr1}^n} + \frac{1}{\tau_{cr2}^n} \quad (13.14)$$

Leiva discussed only in case  $n=1$  but the equation has been written more general for later use. He also considered yielding as a limit for the component critical stresses in an attempt to make a design formula. The idea of Leiva will not be evaluated but it will form the basis for a model that will be presented later called "Combined model".

### 13.3.3 Model according to Lindner [6]

Lindner made an evaluation of test results 0 to 23 in Table 13.1. He discussed different options for taking the interaction between local and global buckling into account, including using (13.14) with  $n=2$ . His conclusions were however that the

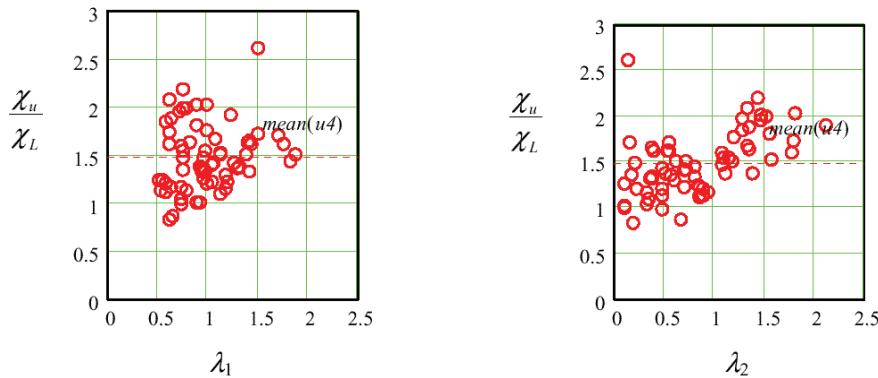

interaction could be taken into account implicitly by correcting  $\lambda_2$ . Lindner's model has been introduced in German recommendations [2]. The reduction factor for the resistance:

$$\chi_{i,L} = \frac{0.588}{\lambda_i} \quad (13.15)$$

is used for both local and global buckling.  $\lambda_1$  is as defined in (13.12) but  $\lambda_2$  is changed according to:

$$\lambda_2 = \sqrt{\frac{2f_y}{\tau_{cr2}\sqrt{3}}} \text{ if } 0.5 < \tau_{cr1}/\tau_{cr2} < 2 \quad (13.16)$$

The model has been evaluated with results shown in Figure 13.5 and in Table 13.2 where  $\chi_L$  is the smallest of  $\chi_{1L}$  and  $\chi_{2L}$  according to (13.15). The right hand diagram in Figure 13.5 shows that the model has a slight bias with respect to  $\lambda_2$ . It is an under-prediction of the resistance that increases with the slenderness for global buckling. Further the model includes discontinuities in the prediction because of the stepwise correction in (13.15).

**Figure 13.5: Test over prediction as function of  $\lambda_1$  and  $\lambda_2$  according to Lindner's model**

### 13.3.4 Model according to Johnson [8]

The model according to Johnson involves three separate checks; one for local buckling, one for global buckling and one for combined local and global buckling. The check for local buckling is done with the post-buckling resistance predicted by:

$$\chi_{1,J} = \frac{0,84}{\lambda_1} < 1,0 \quad (13.17)$$

For the global buckling the critical stress (13.9) is used but with a coefficient 36 instead of 32,4 and without  $(1-\nu^2)$  in the denominator of  $D_x$  which gives more or less the same results. The design strength is taken as 0,5 times the critical stress, which includes a partial safety factor of 1,1. Considering these differences the characteristic reduction factor becomes:

$$\chi_{2J} = \frac{0,61}{\lambda_2^2} \quad (13.18)$$

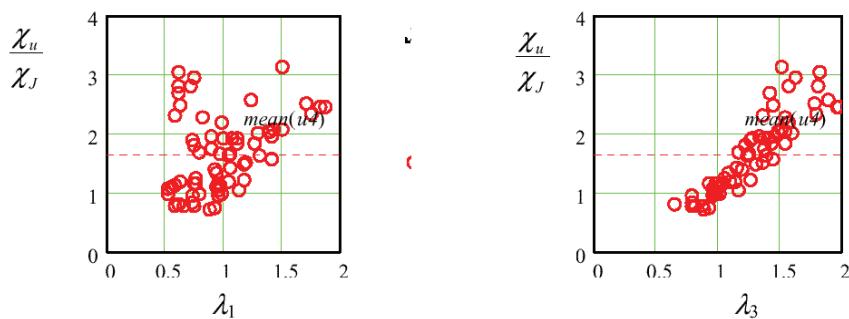

if  $\lambda_2$  is defined by (13.12) and (13.9).

Finally, the interaction between local and global buckling is considered with the critical stress  $\tau_{cr3}$  according to (13.14) with  $n=1$ . The resistance is taken as the critical stress with a reduction factor  $0,67 \times 1,1$ , which leads to the reduction factor:

$$\chi_{3J} = \frac{0,74}{\lambda_3^2} \quad (13.19)$$

where  $\lambda_3$  is defined by (13.12) and (13.14) with  $n=1$ .

The evaluation is shown in Figure 13.6 and Table 13.2.  $\chi_J$  is taken as the lowest value from the three separate checks. The right hand diagram depicting the combined check shows a clear bias for under-prediction for high slenderness values, which is caused by the use of reduced critical stresses as design strength. The scatter in the quotient test over prediction shown in Table 13.2 is also fairly high.

**Figure 13.6: Test over prediction as function of  $\lambda_1$  and  $\lambda_3$  according to Johnson's model**

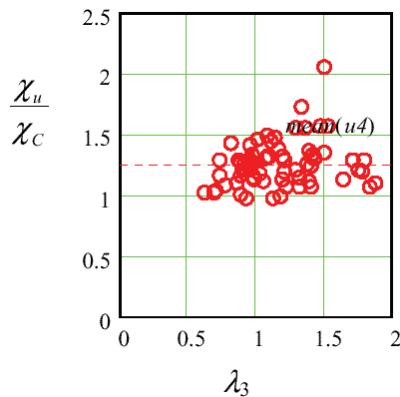

### 13.3.5 Combined model

The basic idea of this model was to define the resistance by a single reduction factor. A reduced critical stress will be defined by (13.14) in order to take the interaction between local and global buckling into account. This critical stress is used to calculate the slenderness parameter  $\lambda_3$  from (13.12). It is used in combination with the strength function:

$$\chi_c = \frac{1,2}{0,9 + \lambda_3} < 1,0 \quad (13.20)$$

The results for  $n=2$  are shown in Table 13.2 and in Figure 13.7. Also  $n=4$  has been checked and the result is quite similar considering the statistical parameters. Both alternatives represent a quite weak interaction and the interaction becomes weaker the higher value of  $n$  is used. It can be seen that this model improves the prediction. However, the model is symmetrical in the influence of local and global buckling. It could be expected on theoretical grounds that the post-critical resistance is more pronounced for local buckling than for global. In the latter case

it is questionable if there is any at all. On the other hand the influence of imperfections in the range of medium slenderness can be expected to be smaller than for local buckling. This became clear when the tests with sinusoidally corrugated webs were included in the comparisons, which was done quite late in the work. This reasoning led to the model described in the next section.

**Figure 13.7: Test over prediction as function of  $\lambda_3$  according to model Combined check,  $n=2$**

### 13.3.6 Model according to EN 1993-1-5

The model is based on the one proposed by Höglund [7]. It has two separate checks, one for local and one for global buckling. It has been modified in [18] and further modification has been done here as will be discussed below. The reduction factors for local and global buckling, respectively, is given by:

$$\chi_{1,EN} = \frac{1.15}{0.9 + \lambda_1} < 1.0 \quad (13.21)$$

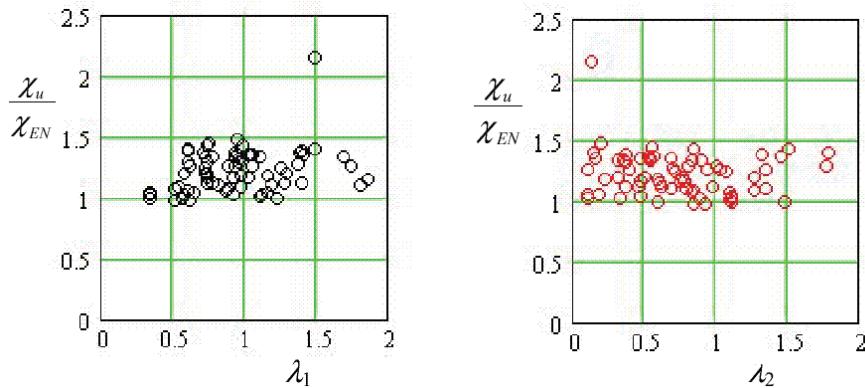

$$\chi_{2,EN} = \frac{1.5}{0.5 + \lambda_2^2} \leq 1.0 \quad (13.22)$$

The reasoning behind the two checks is that the local buckling is expected to show a post-critical strength, which should not be present in the global buckling. This is reflected by  $\lambda_1$  appearing linear and  $\lambda_2$  is squared in the reduction factor. In [18] the reduction factor for local buckling has no plateau but the global buckling has the same reduction factor as (13.17). There is however one more difference. The restraint from the flanges to the global buckling is included in [18] and an increase of the buckling coefficient to 40 is suggested if a certain stiffness criterion is met. The predictions were compared with the test results in Table 13.1 and also with some tests on aluminium girders. The prediction is marginally better than the one using (13.21) and (13.22). The idea of increasing the global buckling coefficient has also been discussed by Leiva and it may very well be true. It has however not been included in the model in EN 1993-1-5 for simplicity and as an additional safety measure. The reduction factors (13.21) and (13.22) are shown in Figure 13.9 together with the Euler curve and the von Karman curve.

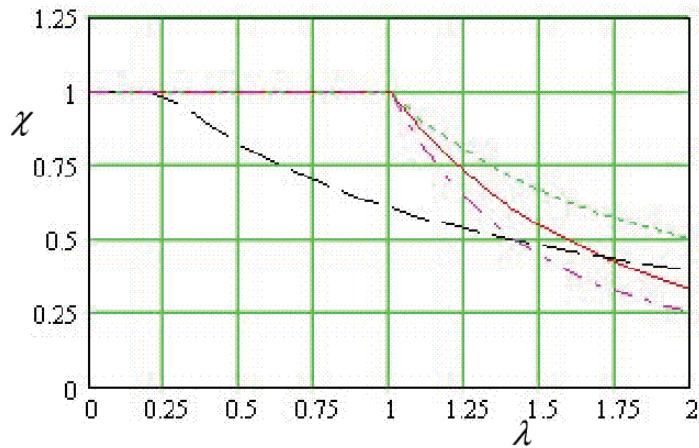

There are no test results that make it possible to evaluate the length of the plateau length for local buckling. Equation (13.21) has a plateau until  $\lambda_1 = 0.25$ , which is

very small compared to other buckling problems. For instance the design rules for flat webs give  $\lambda = 0.83$  for the plateau length with  $\eta = 1$ . This question will remain unsettled until further experiments are available. It is believed that (13.21) is conservative enough.

The evaluation results are found in Figure 13.8 and Table 13.2. The notation  $\chi_{EN}$  is the minimum of (13.21) and (13.22). The prediction is quite good with all the results between 1 and 1,5, except for test 65, which stick out in all the evaluations.

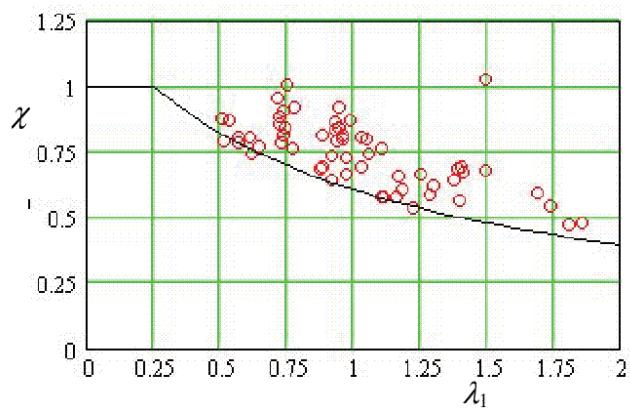

**Figure 13.8: Test over prediction according to the model in EN 1993-1-5**

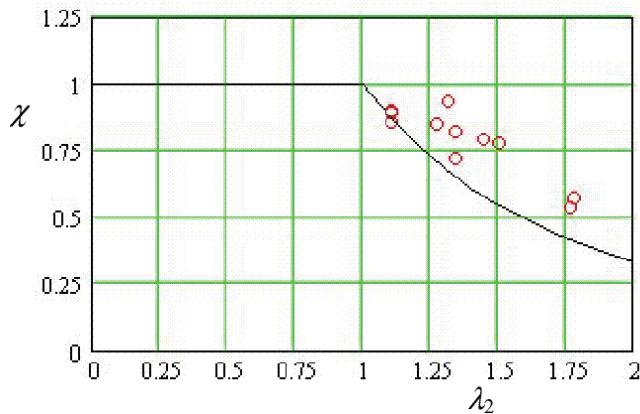

**Figure 13.9: Reduction factors according to EN 1993-1-5; global buckling solid and local buckling dashed. As reference the Euler curve  $1/\lambda^2$  is shown as dash-dots and the von Karman curve  $1/\lambda$  as dots**

Figure 13.10 shows the test results for which local buckling is supposed to govern and Figure 13.11 there global buckling is supposed to govern. The predictions gives almost the same statistical characteristics, mean 1,22 and 1,23 with coefficient of variation 0,15 and 0,14 for local and global buckling, respectively.

### 13.3.7 Discussion

The test data base is quite large and covers a range of parameters for instance:

$$190 < f_y < 690 \text{ Mpa}$$

$$140 < h_w/t_w < 1200$$

$$30^\circ < \alpha < 63^\circ$$

Most of the tests are normal I-girders tested in three or four point bending. The exceptions are test 27 and 28, which were racking tests on container walls with an unsymmetrical corrugation. The report included one more shear test that has been discarded because the web was not continuously welded. Test 65 and 66 had a triangular corrugation ( $a_1$  in Figure 13.2 equal to zero) and the girder had flanges of cold-formed channels. Test 65 showed a very high resistance compared to prediction, which to some extent may have been influenced by the flanges carrying some shear. However, it is not the whole truth as test 66 does not stick out. The tests by Hamilton [15] included four more tests with the remark “support induced failure”, which are not included in Table 13.1.

The normal procedure for dealing with buckling problems is to use the critical stress for defining a slenderness parameter as in (13.12) and to find a reduction factor that depends on this slenderness parameter. In all the models studied here a post critical strength is recognized for the local buckling. It is however less pronounced than for a flat web. This is likely to be so because the folds of the web are less efficient in supporting tension fields than the flanges of a girder with a flat web. One question is how small the angle  $\alpha$  between adjacent panels can be made before the fold becomes insufficient as a support for the panels. The smallest angle in the tests is  $30^\circ$ . This has been taken as lower limit until further evidence is available.

The next question is interaction between the two buckling modes. This has been considered by most of the authors except Höglund. His reasoning is that the interaction, if any, is so weak that two separate checks are sufficient. The evaluation in Table 13.2 supports this opinion as the EN 1993-1-5 model based on Höglund's ideas, shows the lowest scatter. The suggestion of Lindner to increase the slenderness parameter for global buckling if the critical stresses for local and global buckling are close to each other is hard to justify and it creates an unnatural discontinuity. Using (13.14) for defining a reduced critical stress would give a continuous procedure that gives the highest interaction when the two critical stresses are equal. This seems intuitively reasonable. It will however be symmetrical in  $\tau_{cr1}$  and  $\tau_{cr2}$ , which is not likely to be true as indicated in the discussion in 13.3.5. Because of this theoretical objection and that the prediction of the test results is as good with the separate checks this was chosen.

For some low value of the slenderness the shear yield resistance of the web should be reached. The test results do not indicate at which slenderness this will be safely met. From Figure 13.10 it can be seen that the lowest slenderness where local failure was governing is  $\lambda_l=0.5$ . Judging from experiences of other plate buckling phenomena (13.21) will be very safe with  $\lambda_l = 0.25$  for reaching the yield resistance as discussed in 13.3.6.

The design model presented in EN 1993-1-5 has been shown to be a step forward compared to other existing or possible design models. It is certainly not the final

answer to the question of shear resistance of corrugated webs and future research will hopefully improve the model.

### 13.4 Patch loading

No rules for patch loading resistance are given in EN 1993-1-5. The rules for flat webs may be used but this is in most cases quite conservative, especially if the loaded length is larger than one half corrugation  $w$ . The patch loading resistance has been studied by several authors [10], [20], [21]. The results have however not been collated and merged into a design model. In [1] the design rule for patch loading includes only a check of the yield resistance. For sinusoidally corrugated webs for the patch loading resistance has been studied in [22] and [23].

## INTRODUCTION

### The SIN Beam

The SIN Beam is a unique steel structural member with a cold formed steel corrugated steel web element welded to two hot-rolled steel flange plates, resulting in a typical wide flange type section. The only difference being that the web is not a linear equal thickness steel plate but a sinusoidal corrugated cold formed steel section. SIN Beams can be used as flexural members such as roof or floor beams, as compression members such as columns, or as members subjected to combined bending and axial loading such as in moment frames. Shown in Figure 1 is a schematic diagram of the SIN Beam section that is manufactured by Steelcon Fabrication Inc. (Steelcon) in Brampton, Ontario.

Corrugated web steel beams have been researched since the 1960's and have been used in Europe for over 30 years. In fact, Annex D (Plate Girders with Corrugated Webs) of Euro Code EN1993-1-5:2006 (Steel Plated Structural Elements) [1] contains structural design information for such members. The SIN Beam is made using the same equipment and processes that ZEMAN of Austria has been using in Europe for the past 20 years.

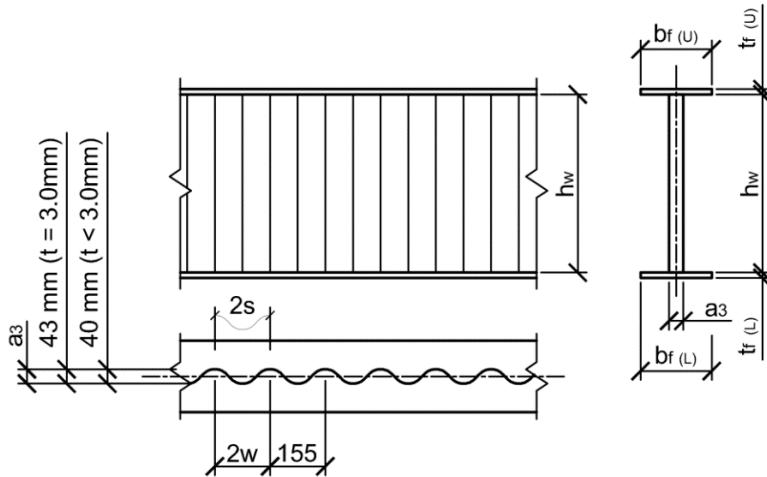

Figure 1 – Schematic Diagram of SIN Beam Section

### Governing American Standards

Since the SIN Beam is made of two different steel materials, 1) flanges that are hot-rolled steel plates, ANSI/AISC 360-16 [2] applies and 2) AISI S100-16 [3] is the Standard that applies for the cold formed steel corrugated web section. In the case of the shear resistance of the SIN Beam, a direct calculation cannot be made based on Chapter G of AISI S100-16 [3], however, Section A1.2

does permit the use of a “*Rational Engineering Analysis*” based on appropriate theory and engineering judgement.

### **Objective**

The primary objective of this report was to establish an appropriate rational engineering analysis for the shear resistance of the SIN Beam and to substantiate this analysis with verification testing.

## **SHEAR RESISTANCE ANALYSIS**

Since Euro Code EN1993-1-5:2006 [1] contains a proven analysis for the shear strength of corrugated steel web members, it was chosen herein as the most appropriate Rational Analysis available in the design Code literature. The nominal shear strength is computed as follows. As can be observed, the theoretical base of this Equation is von Mises yield theory with a shear buckling coefficient relating to the corrugated web of the member.

$$V_n = \chi_c \frac{1}{\sqrt{3}} F_y A_w; \quad \chi_c = \min(\chi_{c,l}, \chi_{c,g})$$

The value of  $\chi_c$  is taken as the lesser value of Local or Global buckling  $\chi_{c,l}$  or  $\chi_{c,g}$ .

### **Local Buckling**

$$\chi_{c,l} = \frac{1.15}{0.9 + \bar{\lambda}_{c,l}} \leq 1.0$$

$$\bar{\lambda}_{c,l} = \sqrt{\frac{F_y}{\tau_{cr,l} \sqrt{3}}}$$

$$\tau_{cr,l} = \left\{ 5.34 + \frac{a_3 s}{h_w t_w} \right\} \frac{\pi^2 E}{1 - \mu^2} \left( \frac{t_w}{s} \right)^2$$

### **Global Buckling**

$$\chi_{c,g} = \frac{1.5}{0.5 + (\bar{\lambda}_{c,g})^2} \leq 1.0$$

$$\bar{\lambda}_{c,g} = \sqrt{\frac{F_y}{\tau_{cr,g} \sqrt{3}}}$$

$$\tau_{cr,g} = \frac{32.4}{t_w (h_w)^2} \sqrt[4]{D_x (D_z)^3}$$

$$D_x = \frac{\pi^2 t_w^3}{1 - \mu^2} \frac{w}{s}$$

$$D_z = \frac{EI_z}{w}$$

Where,

$F_y$  - yield stress of corrugated web

$a_3$  - amplitude of corrugated web

$s$  - unfolded length of one half corrugation wave

$E$  - modulus of elasticity of corrugated web

$\mu$  - poisson's ratio = 0.30

$h_w$  - clear web height of corrugated web

$t_w$  - web thickness of corrugated web

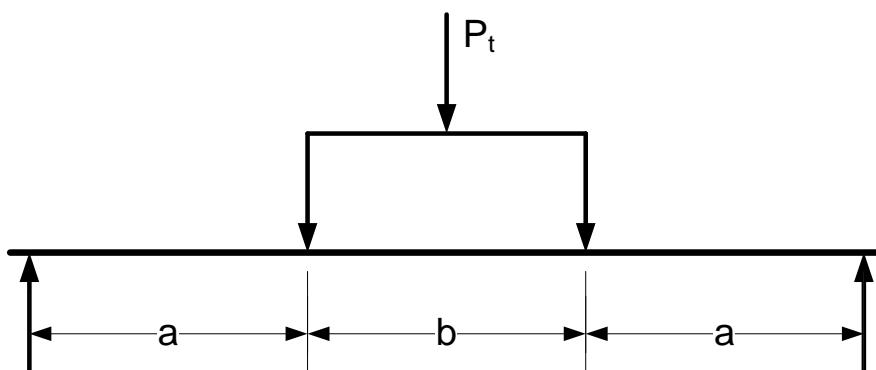

$w$  - length of one half corrugation wave

These buckling coefficients have been developed for steel beams with either trapezoidal or sinusoidal corrugated web configurations. Available research indicates that these coefficients are conservative when applied to steel beams with sinusoidal/corrugated webs such as with the SIN Beam [4], [5]. Extensive testing has been done in Europe to verify the design approach for shear that is contained in Euro Code EN1993-1-5:2006 [1], however, the Steelcon company decided to also carry out such shear tests on the SIN Beam product manufactured in its Canadian Brampton Ontario facility.

## SHEAR TESTING

### General

Steelcon retained “exp Brampton Laboratory” (eBL) to carry out the shear tests of the SIN Beam. Since eBL did not have a structural test frame in their facility with the required capacity, it was decided that Steelcon erect such a test frame in their facility to carry out these tests. All test specimens were fabricated/assembled in the Steelcon plant and actual testing/supervision was performed by the eBL staff. Shown in Figure 2 is a schematic diagram of the shear test set up, where  $a = 5$  ft and  $b = 4$  ft.

**CELL 1****CELL 2****Figure 2 - Schematic Diagram of Shear Test Set up**

Three shear tests were carried out in each case for the SIN WTB500/178x16 and the SIN WTA1000/178x10 beams. Two load cells were used to apply the load, CELL 1 and CELL 2. Shown in Figure 3 is a typical shear failure, which I personally witnessed.

**Figure 3 – Typical Shear Failure****TEST RESULTS AND COMPARISONS**

The test data from Reference 6 is contained in Appendix A of this report. More specifically, Table A1 contains the mechanical properties of the steel. Summarized in Table A2 are the shear test results and the respective calculated values with comparisons. The lesser load of load CELL 1 and load CELL 2 was used as the test shear value,  $V_t$ . As can be observed from Table A2, the average shear test ratio,  $V_t/V_n$ , in each case is equal to or greater than 1. This indicates that the shear prediction method selected from Reference 1 is an appropriate Rational Analysis method. The calculated nominal shear strengths are presented in Tables B1 and B2 of Appendix B.

**CONCLUSIONS**

Based on the information presented herein, the EN1993-1-5:2006 [1] design method satisfies the requirements of AISI S100-16 [3] and can be used for computing the nominal shear strength,  $V_n$ , of

the SIN Beam. The available shear strength,  $V_a$ , can then be computed as follows using either design method:

ASD

$$V_a = V_n / \Omega; \quad \Omega = 2.00$$

LRFD

$$V_a = \phi V_n; \quad \phi = 0.80$$

where  $\Omega = 2.00$  and  $\phi = 0.80$  are given in Section A1.2(c) [3].
